

In this essay, we continue our study of the 1,000 most-cited contemporary scientists. In Part 1 we provided the entire list of authors. ${ }^{1}$ Part 2A examined data for 214 authors in the physical and chemical sciences. ${ }^{2}$ This essay covers 267 authors in the first of three groups of life sciences disciplines. The remaining life scientists will be covered in two more essays to follow. The next part will cover immunology, virology, microbiology, physiology, histology, and hematology. The final part will cover 14 other life and clinical sciences disciplines.
The term "contemporary authors" is used because the citation data culled for this analysis were limited to articles published from 1965 to 1978, and indexed in Science Citation Index ${ }^{\circledR}$ (SCI ${ }^{\circledR}$ ). Data for cited books were not included. The list was produced from "all-author" data, meaning that each author was treated as a first author, regardless of his or her position in an article's by-line.
The disciplines included in this essay are biochemistry, biophysics, cell biology, enzymology, genetics, molecular biology, and plant sciences. Classifying scientists by traditional disciplines is a real challenge, especially in the life sciences. A recent book which defines the various branches of biology makes this clear. As Joshua Lederberg writes in the genetics section of the book: "The science of living things is too complicated both in method and in objective
to yield to tidy classification." ${ }^{3} \mathrm{He}$ goes on to note that genetics is "a particular way of looking at almost every aspect of biology." The same can perhaps be said for many life sciences disciplines.

Another reason it is often difficult to classify scientists is that many of them work in more than one discipline. And sometimes a scientist will start in a discipline like physics and then "cross over" into molecular biology. Thus, while a particular scientist may have accumulated a massive citation record in one field, he or she may be treated in this study as part of another discipline. Quite often, scientists are ambivalent about their classifications. If a molecular biologist is using the techniques of X-ray crystallography, he or she may have divided loyalties. For example, M. Sundaralingam, University of Wisconsin, chose to be listed here as a biophysicist, but he also considers himself an X-ray crystallographer.
We allowed the authors in this study to classify themselves by checking the appropriate box in a list of specialties included in a questionnaire. Not surprisingly, we found considerable disciplinary overlap. For example, many authors checked biochemistry as well as other disciplines, sometimes as many as three or four. In cases where authors checked more than one box, we used other methods to "pigeonhole" them. Since the publication of the original list of 1,000 authors, two of the authors listed

Table 1: The most-cited scientists in the preclinical basic sciences (first group), listed alphabetically by fields. Date of birth is in parentheses. $A=$ total citations. $B=$ first author citations. $\mathrm{C}=$ citations as a secondary author. $\mathrm{D}=$ total number of cited papers. $\mathrm{E}=$ first author papers. $\mathrm{F}=$ secondary-authored papers. $\mathrm{G}=$ citations/paper. Academy memberships are indicated by a code in column H. A key to these codes appears in Table 2. Asterisks indicate Nobel prizewinners.

here, by their own request, have been reclassified-C. H. Li from pharmacology to biochemistry, and Fritz A. Lipmann from microbiology to biochemistry.

Table 1 lists the 267 authors in this group of life sciences disciplines. Their names are listed alphabetically below the appropriate discipline heading. The table contains information about each author's citations and number of cited papers. Taken all together, the authors in this section received more citations as secondary authors than as primary authors of journal articles. They also published more cited papers as secondary authors than as primary authors.

The citation rate given in column $G$ is the average number of citations per cited paper. For example, K. Fuxe's 238 cited papers received 13,319 citations. The rate of citation is 55 . On the other hand, G. Felsenfeld's 36 cited papers received 3,200 citations for a citation rate of 88 .

Do not attribute special significance to small differences in individual citation counts. Keep in mind that even a list of 1,000 authors accounts for just .2 percent of regularly publishing scientists in the world. Therefore, while virtually all of the authors presented here are of Nobel class, ${ }^{4}$ we have probably excluded from this study a large number of very important scientists.

Included in Table 1 is each author's year of birth. This group includes the oldest of the 1,000 , Lipmann, Nobel laureate and professor of biochemistry, Rockefeller University. Lipmann was born in 1899, and coauthored his mostcited paper in this study when he was 72 years old.s

Since the publication of the first essay in this series in October 1981, I was saddened to hear of the death of Hans Krebs, who appears in this group of authors. In 1953, Krebs won the Nobel prize for his discovery of the citric acid cycle, now commonly known as the

Krebs cycle. ${ }^{6}$ Krebs was a member of the SCI editorial advisory board and inspired much of my work with continued encouragement over the years. We have also learned from Mrs. Zora Sormová that František Šorm, whose name appeared in Part 2A, died in November 1980. Sorm had been director of the Institute of Organic Chemistry and Biochemistry of the Czechoslovakian Academy of Sciences, of which he formerly served as president. He served on the editorial board of Curremt Abstracts of Chemistry and Index Chemicus ${ }^{8}$. These great scientists and humanitarians are mourned by their colleagues throughout the world.

The asterisks in Table 1 identify Nobel laureates. Along with Lipmann and Krebs, there are 13 other Nobelists in this group. Six are from molecular biology, five from biochemistry, two from cell biology, and one each from biophysics and genetics.

Fewer than half (130) of the scientists listed here are members of national academies. (The letters in column H of Table 1 denote academy memberships, while Table 2 provides a key to these letter codes.) Although the majority of scientists listed under molecular biology, biophysics, enzymology, and genetics are academy members, less than half of the biochemists, cell biologists, and plant scientists hold academy memberships. Thirteen authors in this group are members of more than four academies. They are listed in Table 3.

As this essay went to press, the US National Academy of Sciences (NAS) admitted 60 new members and 12 foreign associates to the academy. Of these, 17 appear in the list of 1,000 authors in Part 1. This raises the number of NAS members in this study to 257. The 17 new members will be identified in the next essay in this series.

Table 4 provides citation and authorship data for the disciplines in this

spectrum of interests, rather than just a few "hot spots."' Enzymology and plant sciences have just six authors each on the list.

The cell biologists average more citations per author, 4,175 , than any other discipline in this group. Only the biochemists also averaged more than 4,000 . The six enzymologists averaged more cited papers, 117, than authors in the other disciplines. The plant scientists are the oldest authors here with an average age of 62 years. When we performed our studies of botany journals, ${ }^{8,9}$ plant biologist Jacob Levitt, Carnegie Institution, Stanford, California, provided some of the reasons plant scientists will cite biochemical papers, and why the reverse may not be true. ${ }^{10}$ It is interesting that citation practices are reflected in the way plant scientists are represented in the academies. Incidentally, a group of six histologists, to be covered in the next part, conceivably might have been grouped with the cell biologists.

Our look at the physical and chemical scientists contained a brief discussion of some of the difficulties in assigning credit for citations to multiauthored works. In a letter to Science," Derek J. de Solla Price argues that it is absurd to give all authors on a large team equal credit to that received by someone who is sole author of a highly cited paper. Price has proposed that such credit

| Plant Sciences | 6 | 2692 | 882 | 1810 | 72 | 10 | 62 | 1 | 0 | 1920 |

should perhaps be assigned proportionately to each author. For example, a citation to a paper with two authors means that each author receives credit for half of a citation. Three authors of a paper would receive one-third of all citations to that paper.

Using Price's method for assigning credit to multiauthored work, we found that one-quarter of the physicists on our list of 1,000 would drop off. Applying Price's method to the present group of authors, we found that 32 would not have made the list: 15 from biochemistry, five from cell biology, four each from molecular biology and genetics, and two each from biophysics and plant sciences. Interestingly enough, all of the enzymologists would remain on the list if Price's method were applied.
T. C. Hsu, Texas Medical Center, Houston, acknowledges that Price's method of assigning credit is an "improvement," but asserts that it is still unfair to whoever did the really important work. ${ }^{12}$ Hsu recalls a case, a common one, in which a geneticist wanted to study the chromosomes of a hospital patient who died. A pathologist, as the only person authorized to perform autopsies, provided the geneticist with a tissue sample from the patient. In the resulting paper, the pathologist appeared as coauthor, although he contributed nothing to the research. Why, wonders Hsu, should the pathologist
receive equal credit with the geneticist? Why indeed! It seems to me that many scientists are unwilling to deal strongly with the ethical issues of authorship. ${ }^{13}$

Hsu suggests that credit should perhaps be distributed like prize money in a golf tournament. The tournament winner gets the full amount of the prize, the runner-up gets half that amount, and the third-place golfer gets half the amount of the second. Similarly, the first author of a paper would get full credit for each citation, the second author would get credit for half a citation, and the third author would get credit for one-fourth. However, Hsu doesn't believe that any credit should be assigned beyond the fourth author. He again cites the case of the geneticist and the pathologist above, noting that by the time the paper was published, "the pediatricians, the endocrinologist, and other clinicians also got their names in a 7 - or 8 -authored article." 12

The point of Hsu's anecdote is well taken, but there is as yet no statistical evidence that such cases affect the ranking of scientists who regularly publish work of high impact. The unnamed pathologist may be one of thousands who publish but rarely and need an occasional paper to bolster their careers at a local level. Of greater concern are those in positions of power who abuse that power to gain greater visibility. Journals should require that authors
sign a statement not unlike those found in patent applications. This would cover the exact nature of the contribution made by each author.

But while some abuse their power, I believe they represent a small percentage of the scientists we have identified as prolific. Those who consistently publish work of high caliber often place themselves at the end of the by-line. It would be absurd to conclude that they con-
tributed the least. Until professional societies establish clear and unambiguous guidelines on these matters, we cannot criticize individuals for breaking unwritten laws.

My thanks to Thomas Di Julia and Patricia Heller for their help in the preparation of this essay.
