Volume 11 of *Essays of an Information Scientist*, with a Foreword by Baruch S. Blumberg

Numbers 52-53

December 24-31, 1990

Essays of an Information Scientist: Science Literacy, Policy, Evaluation, and Other Essays is now available. This is the 11th volume of a series that began in 1977, with publication of two volumes of essays written intermittently from 1962 to 1976. Volumes 3 through 5 each covered two years of *Current Comments*® between 1977 and 1982, while volumes 6 through 11 each cover one year from 1983 to 1988. Volumes 12 and 13 are in preparation.

Thumbing through volume 11, I was struck by the enormous changes in the world in the short time since these essays appeared. This is particularly true of the events in Eastern Europe and the USSR, where greater scientific collaboration with the West is blossoming. In my last essay for 1988, I discussed international science policy and outlined the structure and management of R&D in the USSR.

Other topics beside those in the subtitle include hibernation and chronobiology, snake venom, and depletion of the ozone layer. And, of course, new tools announced by ISI® that year, such as the *Science Citation Index*® *Compact Disc Edition*, were discussed, emphasizing their use in studying the history and structure of science.

Foreword by Baruch S. Blumberg

I'm honored that Nobel laureate Baruch S. Blumberg, Fox Chase Cancer Center, Philadelphia, and Balliol College, Oxford University, UK, wrote the foreword to this volume of essays. It is reprinted here.^{1,2} Unfortunately, the annual series of articles I've done on the Nobel Prizes did not begin until 1979, three years after Barry shared the

1976 Nobel Prize in physiology or medicine for his discovery concerning new mechanisms for the origin and dissemination of infectious diseases.

In the early 1960s, Blumberg studied many thousands of blood samples taken from such diverse human beings as Asians, Africans, and American Indians in an attempt to discover how genetic variations influence susceptibility to disease.³

In 1963, he studied the blood serum of an Australian aborigine. He discovered that the serum contained an antigen that reacted with an antibody in the serum of a transfused patient with hemophilia. The patient apparently had acquired the antibody from an unidentified blood donor in the course of a blood transfusion.⁴

Later, Blumberg and his colleagues established that the Australia antigen was part of a virus that causes the most severe form of hepatitis—hepatitis B. He followed this discovery with evidence that the virus can cause primary liver cancer—a major health problem in many parts of the world, but a rarity in the US. He commented on this in his *Citation Classics*® in *Current Contents*® in 1979.^{5,6}

Blumberg was in the departments of medicine and anthropology at the University of Pennsylvania, Philadelphia. He returned to academic life in 1989 when he became the master of Balliol College at Oxford University, UK, from where he received his doctorate in biochemistry in 1955. He also taught there as a visiting professor in 1983-1984.⁷

Volume 11 contains a reprint of an article by another Nobel laureate, Joshua Lederberg, now president emeritus and professor at The Rockefeller University, New York. His article concerns the discovery of genetic

recombination in bacteria, for which he received the prize in 1958.⁸

This volume also has one of my favorites—a tongue-in-cheek essay inspired by Art Buchwald on the fictional “International School of Professional Ethics,” the ultimate source of expertise on scientific fraud. Other less amusing topics include noninvasive medicine, embryology, midwifery, and sleep deprivation in medicine.

Although I certainly lack Humboldt’s comprehension of all things scientific, let me say, as I note in the Preface to this vol-

ume, that my appreciation of science as it really is—warts and all—is lacking. One essay discusses the etiology and biology of warts, while another is devoted to their treatment.

Readers interested in acquiring *Essays of an Information Scientist* should write to ISI Customer Service, 3501 Market Street, Philadelphia, Pennsylvania 19104. The price of each volume, including index, is \$35. All 11 volumes are available for \$300, which includes a cumulative index to the first 10 volumes.

FOREWORD

Late in his long and intensive life, Baron Alexander von Humboldt embarked on an attempt to synthesize all that was known of the natural world. He called this work, first published in 1847, *Kosmos*—that is, an orderly, harmonious, systematic universe.

The goal of this massive compilation of zoology, botany, terrestrial magnetism, climatology, geology, geography, and more, was to create a grand summation and to see in this assembled mass a unity and an illuminating clarity on which all knowledge could be structured. Humboldt was said to have been the last scientist capable of comprehending all the scientific data of his day, for the sheer amount of information which accumulated afterwards could never be assimilated by a single person. Unfortunately, Humboldt’s brave attempt was unsuccessful, as others have been since they depend on the assumption that the world is finite; that all that is knowable will be known. But we now know that the very process of science may make this impossible. The more questions that are answered, the more are asked; and the experiments and observations the new questions generate continually multiply the store of knowledge which must now be fit into an explainable system.

Does that mean we are confronted with Chaos, the word whose meaning is the exact opposite of Humboldt’s *Kosmos*? The answer to this weighty question is probably “no.” Although we cannot encompass all of knowledge in a simple synthesis, the business of science is to find patterns which bind together a circumscribed body of data, and this can be accomplished.

Eugene Garfield has made an outstanding contribution to the construction of ordered patterns in the world of science. His medium has not been the original data itself, but the perceptions of the scientists who investigate nature's unknowns. Patterns are assembled at different levels. *Current Contents*[®] orders information according to its location in disciplinary and other journals. The *Science Citation Index*[®] (*SCI*[®]) orders knowledge in that it reveals who has referred to a particular article and thereby links the separate projects. Co-citation gives a quantitative measure of relatedness in that it indicates how often two or more papers are cited together. Another method measuring similarity is by bibliographic coupling based on the presumption that the number of cited references shared by two or more papers quantitates relatedness. From these co-citations, clusters of papers which derive from similar interests can be identified and linked with each other and the papers in which they are frequently co-cited. This leads to a two-dimensional diagram that includes a time element allowing the construction of a history of citation events. These can be linked in a complex network, modeling a pattern of scientific activities in a "research front" which is not only a history of events, but implies that future directions can be inferred or even recommended.

There is an additional very exciting potential use of the new CD-ROM edition of *SCI*. The total file can be searched and associations among research activities not obvious from their titles uncovered. If one defines a "new idea" as the recognition of an association of ideas not previously known, then these word searches could become a generator of innovation.

Garfield has cautioned that the patterns obtained from the literature data bases are derivative in nature. For example, the patterns obtained from the clusters can be termed "opinion polls" of those papers deemed important by scientists in the field. An early use of the co-citation methods was the construction of a two-dimensional time-related history of publications on the discovery of hepatitis B and the medical and scientific applications which derived from it. There was little doubt that this analysis gave an indication of how the published papers were related. But scientists who have participated in the discovery recognized that it bore only a partial relation to the actual history of events, much of which had not been published or had been published late in the sequence of research in historical reviews. Hence, the history as related by the co-citation analysis is indeed a history, but not the only chronicle of interest to historians of science.

A special character of Gene's genius is that he has had, and continues to have, the ability to transform ideas into practical realities. Practical not only in the sense that they are useful to scientific workers, but that they are commercially valuable. It is a rare scientist, or any person for that matter, who can see the product of their intellect and imagination converted into an actuality that other people are prepared to pay for; this provides at least one test for validity.

The success of ISI[®], the company founded by Garfield in 1960, is no small achievement. It has made an important contribution to the high-tech business environment of Philadelphia, interacting extensively with the large biomedical and academic activities of the city. It's a major Philadelphia industry.

A consistent feature of these volumes of *Essays of an Information Scientist* is the great diversity of interest that is expressed in their selection. I have inferred that this is an expression of the wide-ranging intellect of the author, who recognizes the enormous extent of knowledge that is knowable and the optimistic view that, using the bibliographic devices that he and his colleagues have devised, it can be integrated into the vast body of information already collected and indexed.

This volume of essays includes an analysis of the Nobel Prizes of the previous year. Sleep deprivation and hibernation are among the several articles on biological and medical topics. There is an interesting biography of Sir Henry Wellcome, an American who made a significant contribution to the British pharmaceutical industry. The company he helped found is now very much in the public eye since it was the first producer of AZT for the treatment of AIDS.

The reflective guest essay by Joshua Lederberg is a fascinating personal account of scientific discovery—in fact, a classic of that genre. The discussion of science education in schools is particularly timely, if somewhat depressing. This is surely one of the most pressing problems facing scientists and one which has not been seriously regarded by the research community. I hope that Garfield's essays still to be written will focus additional attention on it.

A recurrent feature of the Forewords to the volumes of essays has been an account of how the author first encountered Gene Garfield. Well, I can't remember; it seems to me I've always known him, at least as long as I've been in Philadelphia. However, I can say why we have continued to be friends; but this requires a lengthy preamble.

In 1957 I did a season of field work in Nigeria. Although I traveled extensively, particularly in the north, most of my time was spent in the west, in Yorubaland. While there, I learned about the age clubs that were common in the culture of the Yoruba. People born in about the same year would band together in societies which would organize parties, excursions, and other communal social events. This seemed to be an excellent idea; people born about the same time share a great deal and are likely to "understand" each other better than others might. When I returned to the United States, I formed a 1925 club for people born in the same year as I. Gene is a valued member of that club, and we often discuss the virtue of being born in that relatively benign time, a period before the Great Depression, after the First and before the Second World War. The greatest disaster that year was the destruction of the airship "Shenandoah" and the only war of any significance the Grand Chaco War, which has probably escaped the memory of most. It was an optimistic and promising period and, we would like to believe, has imparted its special character on those who were born then. Whether this has in fact happened is immaterial since many '25er's believe that it has.
